

**IN THE SPECIFICATION:**

**Please amend the specification beginning on page 2 at line 25 and ending on page 3 at line 11 as follows:**

In the MPEG format, when a P picture or a B picture is processed, since these pictures use an inter-frame motion compensation predictive process, the circuit scale of an encoder/decoder becomes large and the number of a software process steps remarkably increases. Thus, such a process is not suitable for a small, light, and inexpensive recording/reproducing apparatus such as a digital camera. To solve such a problem, it is necessary to generate an MPEG stream composed of only I pictures. However, MPEG1 (ISO-1172-2) standard defines that the minimum frame rate is either 23.97 MHz (PAL) or 29.97 (NTSC). Thus, it is difficult to form a stream composed of only I pictures without P pictures or B pictures due to the restriction of the frame rate.
